(54) Title: **CROSS TALK REDUCTION FOR ELECTRICAL CONNECTORS**

(57) Abstract: Lightweight, low cost, high density electrical connectors are disclosed that provide impedance controlled, high-speed, low interference communications, even in the absence of shields between the contacts, and that provide for low insertion loss. Signal contacts (S) and ground contacts (G) within the connectors can be scaled and positioned relative to one another such that a differential signal in a first differential pair produces a high field (H) in the gap between the contacts that form the signal pair and a low field (L) near an adjacent signal pair.

## CROSS TALK REDUCTION FOR ELECTRICAL CONNECTORS

5

**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a continuation-in-part of co-pending U.S. Patent Application No. 09/990,794, filed November 14, 2001, and co-pending U.S. Patent Application No. 10/155,786, filed May 24, 2002, the contents of each of which are hereby incorporated by reference.

10

**FIELD OF THE INVENTION**

Generally, the invention relates to the field of electrical connectors. More particularly, the invention relates to lightweight, low cost, high density electrical connectors that provide impedance controlled, high-speed, low interference communications, even in the absence of shields between the contacts, and that provide for a variety of other benefits not found in prior art connectors.

15

**BACKGROUND OF THE INVENTION**

Electrical connectors provide signal connections between electronic devices using signal contacts. Often, the signal contacts are so closely spaced that undesirable interference, or "cross talk," occurs between adjacent signal contacts. As used herein, the term "adjacent" refers to contacts (or rows or columns) that are next to one another. Cross talk occurs when one signal contact induces electrical interference in an adjacent signal contact due to intermingling electrical fields, thereby compromising signal integrity. With electronic device miniaturization and high speed, high signal integrity electronic communications becoming more prevalent, the reduction of cross talk becomes a significant factor in connector design.

20

25

One commonly used technique for reducing cross talk is to position separate electrical shields, in the form of metallic plates, for example, between adjacent signal contacts. The shields act to block cross talk between the signal contacts by blocking the intermingling of the contacts' electric fields. FIGs. 1A and 1B depict exemplary contact arrangements for electrical connectors that use shields to block cross talk.

30

FIG. 1A depicts an arrangement in which signal contacts S and ground contacts G are arranged such that differential signal pairs S+, S- are positioned along

columns 101-106. As shown, shields 112 can be positioned between contact columns 101-106. A column 101-106 can include any combination of signal contacts S+, S- and ground contacts G. The ground contacts G serve to block cross talk between differential signal pairs in the same column. The shields 112 serve to block cross talk between differential  
5 signal pairs in adjacent columns.

FIG. 1B depicts an arrangement in which signal contacts S and ground contacts G are arranged such that differential signal pairs S+, S- are positioned along rows 111-116. As shown, shields 122 can be positioned between rows 111-116. A row 111-116 can include any combination of signal contacts S+, S- and ground contacts G. The  
10 ground contacts G serve to block cross talk between differential signal pairs in the same row. The shields 122 serve to block cross talk between differential signal pairs in adjacent rows.

Because of the demand for smaller, lower weight communications equipment, it is desirable that connectors be made smaller and lower in weight, while  
15 providing the same performance characteristics. Shields take up valuable space within the connector that could otherwise be used to provide additional signal contacts, and thus limit contact density (and, therefore, connector size). Additionally, manufacturing and inserting such shields substantially increase the overall costs associated with manufacturing such connectors. In some applications, shields are known to make up 40% or more of the cost  
20 of the connector. Another known disadvantage of shields is that they lower impedance. Thus, to make the impedance high enough in a high contact density connector, the contacts would need to be so small that they would not be robust enough for many applications.

The dielectrics that are typically used to insulate the contacts and retain them in position within the connector also add undesirable cost and weight.

25 Therefore, a need exists for a lightweight, high-speed electrical connector (i.e., one that operates above 1 Gb/s and typically in the range of about 10 Gb/s) that reduces the occurrence of cross talk without the need for separate shields, and provides for a variety of other benefits not found in prior art connectors.

## BRIEF SUMMARY OF THE INVENTION

The invention provides high speed connectors (operating above 1 Gb/s and typically in the range of about 10 Gb/s) wherein differential signal pairs and ground contacts are arranged so as to limit the level of cross talk between adjacent differential signal pairs. Such a connector can include a first differential signal pair positioned along a first contact column and a second differential signal pair positioned adjacent to the first signal pair along a second contact column. The connector can be, and preferably is, devoid of shields between the first signal pair and the adjacent signal pair. The contacts are arranged such that a differential signal in the first signal pair produces a high field in the gap between the contacts that form the signal pair, and a low field near the second signal pair.

Such connectors also include novel contact configurations for reducing insertion loss and maintaining substantially constant impedance along the lengths of contacts. The use of air as the primary dielectric to insulate the contacts results in a lower weight connector that is suitable for use as a right angle ball grid array connector.

## BRIEF DESCRIPTION OF THE DRAWINGS

The invention is further described in the detailed description that follows, by reference to the noted drawings by way of non-limiting illustrative embodiments of the invention, in which like reference numerals represent similar parts throughout the drawings, and wherein:

FIGs. 1A and 1B depict exemplary contact arrangements for electrical connectors that use shields to block cross talk;

FIG. 2A is a schematic illustration of an electrical connector in which conductive and dielectric elements are arranged in a generally "T" shaped geometry;

FIG. 2B depicts equipotential regions within an arrangement of signal and ground contacts;

FIG. 3A illustrates a conductor arrangement used to measure the effect of offset on multi-active cross talk;

FIG. 3B is a graph illustrating the relationship between multi-active cross talk and offset between adjacent columns of terminals in accordance with one aspect of the invention;

FIG. 3C depicts a contact arrangement for which cross talk was determined in a worst case scenario;

FIGs. 4A-4C depict conductor arrangements in which signal pairs are arranged in columns;

FIG. 5 depicts a conductor arrangement in which signal pairs are arranged in rows;

5                   FIG. 6 is a diagram showing an array of six columns of terminals arranged in accordance with one aspect of the invention;

FIG. 7 is a diagram showing an array of six columns arranged in accordance with another embodiment of the invention;

10                  FIG. 8 is a perspective view of an illustrative right angle electrical connector, in accordance with the invention;

FIG. 9 is a side view of the right angle electrical connector of FIG. 8;

FIG. 10 is a side view of a portion of the right angle electrical connector of FIG. 8 taken along line A-A;

15                  FIG. 11 is a top view of a portion of the right angle electrical connector of FIG. 8 taken along line B-B;

FIG. 12 is a top cut-away view of conductors of the right angle electrical connector of FIG. 8 taken along line B-B;

FIG. 13 is a side cut-away view of a portion of the right angle electrical connector of FIG. 8 taken along line A-A;

20                  FIG. 13A is a cross-sectional view taken along line C-C of FIG. 13;

FIG. 14 is a perspective view of illustrative conductors of a right angle electrical connector according to the invention;

FIG. 15 is a perspective view of another illustrative conductor of the right angle electrical connector of FIG. 8;

25                  FIG. 16A is a perspective view of a backplane system having an exemplary right angle electrical connector;

FIG. 16B is a simplified view of an alternative embodiment of a backplane system with a right angle electrical connector;

30                  FIG. 16C is a simplified view of a board-to-board system having a vertical connector;

FIG. 17 is a perspective view of the connector plug portion of the connector shown in FIG. 16A;

FIG. 18 is a side view of the plug connector of FIG. 17;

FIG. 19 is a side view of a lead assembly of the plug connector of FIG. 17;

FIG. 19B depicts the lead assembly of FIG. 19 during mating;

FIG. 20 is a side view of two columns of terminals in accordance with one embodiment of the invention;

FIG. 21 is a front view of the terminals of FIG. 20;

5        FIG. 22 is a perspective view of a receptacle in accordance with another embodiment of the invention;

FIG. 23 is a side view of the receptacle of FIG. 22;

FIG. 24 is a perspective view of a single column of receptacle contacts;

10       FIG. 25 is a perspective view of a connector in accordance with another embodiment of the invention;

FIG. 26 is a side view of a column of right angle terminals in accordance with another aspect of the invention;

FIGs. 27 and 28 are front views of the right angle terminals of Figure 26 taken along lines A-A and lines B-B respectively;

15       FIG. 29 illustrates the cross section of terminals as the terminals connect to vias on an electrical device in accordance with another aspect of the invention;

FIG. 30 is a perspective view of a portion of another illustrative right angle electrical connector, in accordance with the invention;

20       FIG. 31 is a perspective view of another illustrative right angle electrical connector, in accordance with the invention;

FIG. 32 is a perspective view of an alternative embodiment of a receptacle connector; and

FIG. 33 is a flow diagram of a method for making a connector in accordance with the invention.

## DETAILED DESCRIPTION OF THE INVENTION

Certain terminology may be used in the following description for convenience only and should not be considered as limiting the invention in any way. For example, the terms “top,” “bottom,” “left,” “right,” “upper,” and “lower” designate directions in the figures to which reference is made. Likewise, the terms “inwardly” and “outwardly” designate directions toward and away from, respectively, the geometric center of the referenced object. The terminology includes the words above specifically mentioned, derivatives thereof, and words of similar import.

### 10 I-SHAPED GEOMETRY FOR ELECTRICAL CONNECTORS - THEORETICAL MODEL

FIG. 2A is a schematic illustration of an electrical connector in which conductive and dielectric elements are arranged in a generally “I” shaped geometry. Such connectors are embodied in the assignee’s “I-BEAM” technology, and are described and claimed in U.S. Patent No. 5,741,144, entitled “Low Cross And Impedance Controlled Electric Connector,” the disclosure of which is hereby incorporated herein by reference in its entirety. Low cross talk and controlled impedance have been found to result from the use of this geometry.

The originally contemplated I-shaped transmission line geometry is shown in FIG. 2A. As shown, the conductive element can be perpendicularly interposed between two parallel dielectric and ground plane elements. The description of this transmission line geometry as I-shaped comes from the vertical arrangement of the signal conductor shown generally at numeral 10 between the two horizontal dielectric layers 12 and 14 having a dielectric constant  $\epsilon$  and ground planes 13 and 15 symmetrically placed at the top and bottom edges of the conductor. The sides 20 and 22 of the conductor are open to the air 24 having an air dielectric constant  $\epsilon_0$ . In a connector application, the conductor could include two sections, 26 and 28, that abut end-to-end or face-to-face. The thickness,  $t_1$  and  $t_2$  of the dielectric layers 12 and 14, to first order, controls the characteristic impedance of the transmission line and the ratio of the overall height  $h$  to dielectric width  $w_d$  controls the electric and magnetic field penetration to an adjacent contact. Original experimentation led to the conclusion that the ratio  $h/w_d$  needed to minimize interference beyond A and B would be approximately unity (as illustrated in FIG. 2A).

The lines 30, 32, 34, 36 and 38 in FIG. 2A are equipotentials of voltage in the air-dielectric space. Taking an equipotential line close to one of the ground planes and

following it out towards the boundaries A and B, it will be seen that both boundary A or boundary B are very close to the ground potential. This means that virtual ground surfaces exist at each of boundary A and boundary B. Therefore, if two or more I-shaped modules are placed side-by-side, a virtual ground surface exists between the modules and there will be little to no intermingling of the modules' fields. In general, the conductor width  $w_c$  and dielectric thicknesses  $t_1$ ,  $t_2$  should be small compared to the dielectric width  $w_d$  or module pitch (*i.e.*, distance between adjacent modules).

Given the mechanical constraints on a practical connector design, it was found in actuality that the proportioning of the signal conductor (blade/beam contact) width and dielectric thicknesses could deviate somewhat from the preferred ratios and some minimal interference might exist between adjacent signal conductors. However, designs using the above-described I-shaped geometry tend to have lower cross talk than other conventional designs.

## EXEMPLARY FACTORS AFFECTING CROSS TALK BETWEEN ADJACENT CONTACTS

In accordance with the invention, the basic principles described above were further analyzed and expanded upon and can be employed to determine how to even further limit cross talk between adjacent signal contacts, even in the absence of shields between the contacts, by determining an appropriate arrangement and geometry of the signal and ground contacts. FIG. 2B includes a contour plot of voltage in the neighborhood of an active column-based differential signal pair S+, S- in a contact arrangement of signal contacts S and ground contacts G according to the invention. As shown, contour lines 42 are closest to zero volts, contour lines 44 are closest to -1 volt, and contour lines 46 are closest to +1 volt. It has been observed that, although the voltage does not necessarily go to zero at the "quiet" differential signal pairs that are nearest to the active pair, the interference with the quiet pairs is near zero. That is, the voltage impinging on the positive-going quiet differential pair signal contact is about the same as the voltage impinging on the negative-going quiet differential pair signal contact. Consequently, the noise on the quiet pair, which is the difference in voltage between the positive- and negative-going signals, is close to zero.

Thus, as shown in FIG. 2B, the signal contacts S and ground contacts G can be scaled and positioned relative to one another such that a differential signal in a first differential signal pair produces a high field H in the gap between the contacts that form

the signal pair and a low (*i.e.*, close to ground potential) field L (close to ground potential) near an adjacent signal pair. Consequently, cross talk between adjacent signal contacts can be limited to acceptable levels for the particular application. In such connectors, the level of cross talk between adjacent signal contacts can be limited to the point that the need for  
5 (and cost of) shields between adjacent contacts is unnecessary, even in high speed, high signal integrity applications.

Through further analysis of the above-described I-shaped model, it has been found that the unity ratio of height to width is not as critical as it first seemed. It has also been found that a number of factors can affect the level of cross talk between adjacent  
10 signal contacts. A number of such factors are described in detail below, though it is anticipated that there may be others. Additionally, though it is preferred that all of these factors be considered, it should be understood that each factor may, alone, sufficiently limit cross talk for a particular application. Any or all of the following factors may be considered in determining a suitable contact arrangement for a particular connector design:

15 a) Less cross talk has been found to occur where adjacent contacts are edge-coupled (*i.e.*, where the edge of one contact is adjacent to the edge of an adjacent contact) than where adjacent contacts are broad side coupled (*i.e.*, where the broad side of one contact is adjacent to the broad side of an adjacent contact) or where the edge of one contact is adjacent to the broad side of an adjacent contact. The tighter the edge coupling,  
20 the less the coupled signal pair's electrical field will extend towards an adjacent pair and the less the towards the unity height-to-width ratio of the original I-shaped theoretical model a connector application will have to approach. Edge coupling also allows for smaller gap widths between adjacent connectors, and thus facilitates the achievement of desirable impedance levels in high contact density connectors without the need for  
25 contacts that are too small to perform adequately. For example, it has been found than a gap of about 0.3-0.4 mm is adequate to provide an impedance of about 100 ohms where the contacts are edge coupled, while a gap of about 1 mm is necessary where the same contacts are broad side coupled to achieve the same impedance. Edge coupling also facilitates changing contact width, and therefore gap width, as the contact extends through  
30 dielectric regions, contact regions, *etc.*;

b) It has also been found that cross talk can be effectively reduced by varying the "aspect ratio," *i.e.*, the ratio of column pitch (*i.e.*, the distance between adjacent columns) to the gap between adjacent contacts in a given column;

c) The “staggering” of adjacent columns relative to one another can also reduce the level of cross talk. That is, cross talk can be effectively limited where the signal contacts in a first column are offset relative to adjacent signal contacts in an adjacent column. The amount of offset may be, for example, a full row pitch (*i.e.*, distance  
5 between adjacent rows), half a row pitch, or any other distance that results in acceptably low levels of cross talk for a particular connector design. It has been found that the optimal offset depends on a number of factors, such as column pitch, row pitch, the shape of the terminals, and the dielectric constant(s) of the insulating material(s) around the terminals, for example. It has also been found that the optimal offset is not necessarily “on  
10 pitch,” as was often thought. That is, the optimal offset may be anywhere along a continuum, and is not limited to whole fractions of a row pitch (*e.g.*, full or half row pitches).

FIG. 3A illustrates a contact arrangement that has been used to measure the effect of offset between adjacent columns on cross talk. Fast (*e.g.*, 40 ps) rise-time  
15 differential signals were applied to each of Active Pair 1 and Active Pair 2. Near-end crosstalk Nxt1 and Nxt2 were determined at Quiet Pair, to which no signal was applied, as the offset *d* between adjacent columns was varied from 0 to 5.0 mm. Near-end cross talk occurs when noise is induced on the quiet pair from the current carrying contacts in an active pair.

20 As shown in the graph of FIG. 3B, the incidence of multi-active cross talk (dark line in FIG. 3B) is minimized at offsets of about 1.3 mm and about 3.65 mm. In this experiment, multi-active cross talk was considered to be the sum of the absolute values of cross talk from each of Active Pair 1 (dashed line in FIG. 3B) and Active Pair 2 (thin solid line in FIG. 3B). Thus, it has been shown that adjacent columns can be variably offset  
25 relative to one another until an optimum level of cross talk between adjacent pairs (about 1.3 mm, in this example);

d) Through the addition of outer grounds, *i.e.*, the placement of ground contacts at alternating ends of adjacent contact columns, both near-end cross talk (“NEXT”) and far-end cross talk (“FEXT”) can be further reduced;

30 e) It has also been found that scaling the contacts (*i.e.*, reducing the absolute dimensions of the contacts while preserving their proportional and geometric relationship) provides for increased contact density (*i.e.*, the number of contacts per linear inch) without adversely affecting the electrical characteristics of the connector.

By considering any or all of these factors, a connector can be designed that delivers high-performance (*i.e.*, low incidence of cross talk), high-speed (*e.g.*, greater than 1 Gb/s and typically about 10 Gb/s) communications even in the absence of shields between adjacent contacts. It should also be understood that such connectors and techniques, which are capable of providing such high speed communications, are also useful at lower speeds. Connectors according to the invention have been shown, in worst case testing scenarios, to have near-end cross talk of less than about 3% and far-end cross talk of less than about 4%, at 40 picosecond rise time, with 63.5 mated signal pairs per linear inch. Such connectors can have insertion losses of less than about 0.7 dB at 5GHz, and impedance match of about  $100 \pm 8$  ohms measured at a 40 picosecond rise time.

FIG. 3C depicts a contact arrangement for which cross talk was determined in a worst case scenario. Cross talk from each of six attacking pairs S1, S2, S3, S4, S5, and S6 was determined at a "victim" pair V. Attacking pairs S1, S2, S3, S4, S5, and S6 are six of the eight nearest neighboring pairs to signal pair V. It has been determined that the additional affects on cross talk at victim pair V from attacking pairs S7 and S8 is negligible. The combined cross talk from the six nearest neighbor attacking pairs has been determined by summing the absolute values of the peak cross talk from each of the pairs, which assumes that each pair is fairing at the highest level all at the same time. Thus, it should be understood that this is a worst case scenario, and that, in practice, much better results should be achieved.

#### EXEMPLARY CONTACT ARRANGEMENTS ACCORDING TO THE INVENTION

FIG. 4A depicts a connector 100 according to the invention having column-based differential signal pairs (*i.e.*, in which differential signal pairs are arranged into columns). (As used herein, a "column" refers to the direction along which the contacts are edge coupled. A "row" is perpendicular to a column.) As shown, each column 401-406 comprises, in order from top to bottom, a first differential signal pair, a first ground conductor, a second differential signal pair, and a second ground conductor. As can be seen, first column 401 comprises, in order from top to bottom, a first differential signal pair comprising signal conductors S1+ and S1-, a first ground conductor G, a second differential signal pair comprising signal conductors S7+ and S7-, and a second ground conductor G. Each of rows 413 and 416 comprises a plurality of ground conductors G. Rows 411 and 412 together comprise six differential signal pairs, and rows 514 and 515 together comprise another six differential signal pairs. The rows 413 and 416 of ground

conductors limit cross talk between the signal pairs in rows 411-412 and the signal pairs in rows 414-415. In the embodiment shown in FIG. 4A, arrangement of 36 contacts into columns can provide twelve differential signal pairs. Because the connector is devoid of shields, the contacts can be made relatively larger (compared to those in a connector having shields). Therefore, less connector space is needed to achieve the desired impedance.

FIGs. 4B and 4C depict connectors according to the invention that include outer grounds. As shown in FIG. 4B, a ground contact G can be placed at each end of each column. As shown in FIG. 4C, a ground contact G can be placed at alternating ends of adjacent columns. It has been found that the placement of a ground contact G at alternating ends of adjacent columns results in a 35% reduction in NEXT and a 65% reduction in FEXT as compared to a connector having a contact arrangement that is otherwise the same, but which has no such outer grounds. It has also been found that basically the same results can be achieved through the placement of ground contacts at both ends of every contact column, as shown in FIG. 4B. Consequently, it is preferred to place outer grounds at alternating ends of adjacent columns in order to increase contact density (relative to a connector in which outer grounds are placed at both ends of every column) without increasing the level of cross talk.

Alternatively, as shown in FIG. 5, differential signal pairs may be arranged into rows. As shown in FIG. 5, each row 511-516 comprises a repeating sequence of two ground conductors and a differential signal pair. First row 511 comprises, in order from left to right, two ground conductors G, a differential signal pair S1+, S1-, and two ground conductors G. Row 512 comprises in order from left to right, a differential signal pair S2+, S2-, two ground conductors G, and a differential signal pair S3+, S3-. The ground conductors block cross talk between adjacent signal pairs. In the embodiment shown in FIG. 5, arrangement of 36 contacts into rows provides only nine differential signal pairs.

By comparison of the arrangement shown in FIG. 4A with the arrangement shown in FIG. 5, it can be understood that a column arrangement of differential signal pairs results in a higher density of signal contacts than does a row arrangement. However, for right angle connectors arranged into columns, contacts within a differential signal pair have different lengths, and therefore, such differential signal pairs may have intra-pair skew. Similarly, arrangement of signal pairs into either rows or columns may result in inter-pair skew because of the different conductor lengths of different differential signal pairs. Thus, it should be understood that, although arrangement of signal pairs into

columns results in a higher contact density, arrangement of the signal pairs into columns or rows can be chosen for the particular application.

Regardless of whether the signal pairs are arranged into rows or columns, each differential signal pair has a differential impedance  $Z_0$  between the positive conductor  $S_{x+}$  and negative conductor  $S_{x-}$  of the differential signal pair. Differential impedance is defined as the impedance existing between two signal conductors of the same differential signal pair, at a particular point along the length of the differential signal pair. As is well known, it is desirable to control the differential impedance  $Z_0$  to match the impedance of the electrical device(s) to which the connector is connected. Matching the differential impedance  $Z_0$  to the impedance of electrical device minimizes signal reflection and/or system resonance that can limit overall system bandwidth. Furthermore, it is desirable to control the differential impedance  $Z_0$  such that it is substantially constant along the length of the differential signal pair, *i.e.*, such that each differential signal pair has a substantially consistent differential impedance profile.

The differential impedance profile can be controlled by the positioning of the signal and ground conductors. Specifically, differential impedance is determined by the proximity of an edge of signal conductor to an adjacent ground and by the gap between edges of signal conductors within a differential signal pair.

As shown in FIG. 4A, the differential signal pair comprising signal conductors  $S_{6+}$  and  $S_{6-}$  is located adjacent to one ground conductor  $G$  in row 413. The differential signal pair comprising signal conductors  $S_{12+}$  and  $S_{12-}$  is located adjacent to two ground conductors  $G$ , one in row 413 and one in row 416. Conventional connectors include two ground conductors adjacent to each differential signal pair to minimize impedance matching problems. Removing one of the ground conductors typically leads to impedance mismatches that reduce communications speed. However, the lack of one adjacent ground conductor can be compensated for by reducing the gap between the differential signal pair conductors with only one adjacent ground conductor. For example, as shown in FIG. 4A, signal conductors  $S_{6+}$  and  $S_{6-}$  can be located a distance  $d_1$  apart from each other and signal conductors  $S_{12+}$  and  $S_{12-}$  can be located a different distance  $d_2$  apart from each other. The distances may be controlled by making the widths of signal conductors  $S_{6+}$  and  $S_{6-}$  wider than the widths of signal conductors  $S_{12+}$  and  $S_{12-}$  (where conductor width is measured along the direction of the column).

For single ended signaling, single ended impedance can also be controlled by positioning of the signal and ground conductors. Specifically, single ended impedance

is determined by the gap between a signal conductor and an adjacent ground. Single ended impedance is defined as the impedance existing between a signal conductor and ground, at a particular point along the length of a single ended signal conductor.

To maintain acceptable differential impedance control for high bandwidth systems, it is desirable to control the gap between contacts to within a few thousandths of an inch. Gap variations beyond a few thousandths of an inch may cause unacceptable variation in the impedance profile; however, the acceptable variation is dependent on the speed desired, the error rate acceptable, and other design factors.

FIG. 6 shows an array of differential signal pairs and ground contacts in which each column of terminals is offset from each adjacent column. The offset is measured from an edge of a terminal to the same edge of the corresponding terminal in the adjacent column. The aspect ratio of column pitch to gap width, as shown in FIG. 6, is  $P/X$ . It has been found that an aspect ratio of about 5 (*i.e.*, 2 mm column pitch; 0.4 mm gap width) is adequate to sufficiently limit cross talk where the columns are also staggered. Where the columns are not staggered, an aspect ratio of about 8-10 is desirable.

As described above, by offsetting the columns, the level of multi-active cross talk occurring in any particular terminal can be limited to a level that is acceptable for the particular connector application. As shown in FIG. 6, each column is offset from the adjacent column, in the direction along the columns, by a distance  $d$ . Specifically, column 601 is offset from column 602 by an offset distance  $d$ , column 602 is offset from column 603 by a distance  $d$ , and so forth. Since each column is offset from the adjacent column, each terminal is offset from an adjacent terminal in an adjacent column. For example, signal contact 680 in differential pair DP3 is offset from signal contact 681 in differential pair DP4 by a distance  $d$  as shown.

FIG. 7 illustrates another configuration of differential pairs wherein each column of terminals is offset relative to adjacent columns. For example, as shown, differential pair DP1 in column 701 is offset from differential pair DP2 in the adjacent column 702 by a distance  $d$ . In this embodiment, however, the array of terminals does not include ground contacts separating each differential pair. Rather, the differential pairs within each column are separated from each other by a distance greater than the distance separating one terminal in a differential pair from the second terminal in the same differential pair. For example, where the distance between terminals within each differential pair is  $Y$ , the distance separating differential pairs can be  $Y+X$ , where  $Y+X/Y \gg 1$ . It has been found that such spacing also serves to reduce cross talk.

## EXEMPLARY CONNECTOR SYSTEMS ACCORDING TO THE INVENTION

FIG. 8 is a perspective view of a right angle electrical connector according to the invention that is directed to a high speed electrical connector wherein signal  
5 conductors of a differential signal pair have a substantially constant differential impedance along the length of the differential signal pair. As shown in FIG. 8, a connector 800 comprises a first section 801 and a second section 802. First section 801 is electrically connected to a first electrical device 810 and second section 802 is electrically connected to a second electrical device 812. Such connections may be SMT, PIP, solder ball grid  
10 array, press fit, or other such connections. Typically, such connections are conventional connections having conventional connection spacing between connection pins; however, such connections may have other spacing between connection pins. First section 801 and second section 802 can be electrically connected together, thereby electrically connecting first electrical device 810 to second electrical device 812.

15 As can be seen, first section 801 comprises a plurality of modules 805. Each module 805 comprises a column of conductors 830. As shown, first section 801 comprises six modules 805 and each module 805 comprises six conductors 830; however, any number of modules 805 and conductors 830 may be used. Second section 802 comprises a plurality of modules 806. Each module 806 comprises a column of  
20 conductors 840. As shown, second section 802 comprises six modules 806 and each module 806 comprises six conductors 840; however, any number of modules 806 and conductors 840 may be used.

FIG. 9 is a side view of connector 800. As shown in FIG. 9, each module 805 comprises a plurality of conductors 830 secured in a frame 850. Each conductor 830  
25 comprises a connection pin 832 extending from frame 850 for connection to first electrical device 810, a blade 836 extending from frame 850 for connection to second section 802, and a conductor segment 834 connecting connection pin 832 to blade 836.

Each module 806 comprises a plurality of conductors 840 secured in frame 852. Each conductor 840 comprises a contact interface 841 and a connection pin 842.  
30 Each contact interface 841 extends from frame 852 for connection to a blade 836 of first section 801. Each contact interface 840 is also electrically connected to a connection pin 842 that extends from frame 852 for electrical connection to second electrical device 812.

Each module 805 comprises a first hole 856 and a second hole 857 for alignment with an adjacent module 805. Thus, multiple columns of conductors 830 may

be aligned. Each module 806 comprises a first hole 847 and a second hole 848 for alignment with an adjacent module 806. Thus, multiple columns of conductors 840 may be aligned.

Module 805 of connector 800 is shown as a right angle module. That is, a set of first connection pins 832 is positioned on a first plane (*e.g.*, coplanar with first electrical device 810) and a set of second connection pins 842 is positioned on a second plane (*e.g.*, coplanar with second electrical device 812) perpendicular to the first plane. To connect the first plane to the second plane, each conductor 830 turns a total of about ninety degrees (a right angle) to connect between electrical devices 810 and 812.

To simplify conductor placement, conductors 830 can have a rectangular cross section; however, conductors 830 may be any shape. In this embodiment, conductors 830 have a high ratio of width to thickness to facilitate manufacturing. The particular ratio of width to thickness may be selected based on various design parameters including the desired communication speed, connection pin layout, and the like.

FIG. 10 is a side view of two modules of connector 800 taken along line A-A and FIG. 11 is a top view of two modules of connector 800 taken along line B-B. As can be seen, each blade 836 is positioned between two single beam contacts 849 of contact interface 841, thereby providing electrical connection between first section 801 and second section 802 and described in more detail below. Connection pins 832 are positioned proximate to the centerline of module 805 such that connection pins 832 may be mated to a device having conventional connection spacing. Connection pins 842 are positioned proximate to the centerline of module 806 such that connection pins 842 may be mated to a device having conventional connection spacing. Connection pins, however, may be positioned at an offset from the centerline of module 806 if such connection spacing is supported by the mating device. Further, while connection pins are illustrated in the Figures, other connection techniques are contemplated such as, for example, solder balls and the like.

Returning now to illustrative connector 800 of FIG. 8 to discuss the layout of connection pins and conductors, first section 801 of connector 800 comprises six columns and six rows of conductors 830. Conductors 830 may be either signal conductors S or ground conductors G. Typically, each signal conductor S is employed as either a positive conductor or a negative conductor of a differential signal pair; however, a signal conductor may be employed as a conductor for single ended signaling. In addition, such conductors 830 may be arranged in either columns or rows.

In addition to conductor placement, differential impedance and insertion losses are also affected by the dielectric properties of material proximate to the conductors. Generally, it is desirable to have materials having very low dielectric constants adjacent and in contact with as much as the conductors as possible. Air is the most desirable dielectric because it allows for a lightweight connector and has the best dielectric properties. While frame 850 and frame 852 may comprise a polymer, a plastic, or the like to secure conductors 830 and 840 so that desired gap tolerances may be maintained, the amount of plastic used is minimized. Therefore, the rest of connector comprises an air dielectric and conductors 830 and 840 are positioned both in air and only minimally in a second material (e.g., a polymer) having a second dielectric property. Therefore, to provide a substantially constant differential impedance profile, in the second material, the spacing between conductors of a differential signal pair may vary.

As shown, the conductors can be exposed primarily to air rather than being encased in plastic. The use of air rather than plastic as a dielectric provides a number of benefits. For example, the use of air enables the connector to be formed from much less plastic than conventional connectors. Thus, a connector according to the invention can be made lower in weight than convention connectors that use plastic as the dielectric. Air also allows for smaller gaps between contacts and thereby provides for better impedance and cross talk control with relatively larger contacts, reduces cross-talk, provides less dielectric loss, increases signal speed (*i.e.*, less propagation delay).

Through the use of air as the primary dielectric, a lightweight, low-impedance, low cross talk connector can be provided that is suitable for use as a ball grid assembly ("BGA") right-angle connector. Typically, a right angle connector is "off-balance, *i.e.*, disproportionately heavy in the mating area. Consequently, the connector tends to "tilt" in the direction of the mating area. Because the solder balls of the BGA, while molten, can only support a certain mass, prior art connectors typically are unable to include additional mass to balance the connector. Through the use of air, rather than plastic, as the dielectric, the mass of the connector can be reduced. Consequently, additional mass can be added to balance the connector without causing the molten solder balls to collapse.

FIG. 12 illustrates the change in spacing between conductors in rows as conductors pass from being surrounded by air to being surrounded by frame 850. As shown in FIG. 12, at connection pin 832 the distance between conductor S+ and S- is D1. Distance D1 may be selected to mate with conventional connector spacing on first

electrical device 810 or may be selected to optimize the differential impedance profile. As shown, distance D1 is selected to mate with a conventional connector and is positioned proximate to the centerline of module 805. As conductors S+ and S- travel from connection pins 832 through frame 850, conductors S+, S- jog towards each other, culminating in a separation distance D2 in air region 860. Distance D2 is selected to give the desired differential impedance between conductor S+ and S-, given other parameters, such as proximity to a ground conductor G. The desired differential impedance  $Z_0$  depends on the system impedance (e.g., first electrical device 810), and may be 100 ohms or some other value. Typically, a tolerance of about 5 percent is desired; however, 10 percent may be acceptable for some applications. It is this range of 10% or less that is considered substantially constant differential impedance.

As shown in FIG. 13, conductors S+ and S- are positioned from air region 860 towards blade 836 and jog outward with respect to each other within frame 850 such that blades 836 are separated by a distance D3 upon exiting frame 850. Blades 836 are received in contact interfaces 841, thereby providing electrical connection between first section 801 and second section 802. As contact interfaces 841 travel from air region 860 towards frame 852, contact interfaces 841 jog outwardly with respect to each other, culminating in connection pins 842 separated by a distance of D4. As shown, connection pins 842 are positioned proximate to the centerline of frame 852 to mate with conventional connector spacing.

FIG. 14 is a perspective view of conductors 830. As can be seen, within frame 850, conductors 830 jog, either inwardly or outwardly to maintain a substantially constant differential impedance profile along the conductive path.

FIG. 15 is a perspective view of conductor 840 that includes two single beam contacts 849, one beam contact 849 on each side of blade 836. This design may provide reduced cross talk performance, because each single beam contact 849 is further away from its adjacent contact. Also, this design may provide increased contact reliability, because it is a "true" dual contact. This design may also reduce the tight tolerance requirements for the positioning of the contacts and forming of the contacts.

As can be seen, within frame 852, conductor 840 jogs, either inward or outward to maintain a substantially constant differential impedance profile and to mate with connectors on second electrical device 812. For arrangement into columns, conductors 830 and 840 are positioned along a centerline of frames 850, 852, respectively.

FIG. 13A is a cross-sectional view taken along line C-C of FIG. 13. As shown in FIG. 13A, terminal blades 836 are received in contact interfaces 841 such that beam contacts 839 engage respective sides of blades 836. Preferably, the beam contacts 839 are sized and shaped to provide contact between the blades 836 and the contact interfaces 841 over a combined surface area that is sufficient to maintain the electrical characteristics of the connector during mating and unmating of the connector.

As shown in FIG. 13A, the contact design allows the edge-coupled aspect ratio to be maintained in the mating region. That is, the aspect ratio of column pitch to gap width chosen to limit cross talk in the connector, exists in the contact region as well, and thereby limits cross talk in the mating region. Also, because the cross-section of the unmated blade contact is nearly the same as the combined cross-section of the mated contacts, the impedance profile can be maintained even if the connector is partially unmated. This occurs, at least in part, because the combined cross-section of the mated contacts includes no more than one or two thickness of metal (the thicknesses of the blade and the contact interface), rather than three thicknesses as would be typical in prior art connectors (see FIG. 13B, for example). Unplugging a connector such as shown in FIG. 13B results in a significant change in cross-section, and therefore, a significant change in impedance (which causes significant degradation of electrical performance if the connector is not properly and completely mated). Because the contact cross-section does not change dramatically as the connector is unmated, the connector (as shown in FIG. 13A) can provide nearly the same electrical characteristics when partially unmated (*i.e.*, unmated by about 1-2 mm) as it does when fully mated.

FIG 16A is a perspective view of a backplane system having an exemplary right angle electrical connector in accordance with an embodiment of the invention. As shown in Figure 16A, connector 900 comprises a plug 902 and receptacle 1100.

Plug 902 comprises housing 905 and a plurality of lead assemblies 908. The housing 905 is configured to contain and align the plurality of lead assemblies 908 such that an electrical connection suitable for signal communication is made between a first electrical device 910 and a second electrical device 912 via receptacle 1100. In one embodiment of the invention, electrical device 910 is a backplane and electrical device 912 is a daughtercard. Electrical devices 910 and 912 may, however, be any electrical device without departing from the scope of the invention.

As shown, the connector 902 comprises a plurality of lead assemblies 908. Each lead assembly 908 comprises a column of terminals or conductors 930 therein as will be described below. Each lead assembly 908 comprises any number of terminals 930.

FIG. 16B is backplane system similar to FIG. 16A except that the connector 903 is a single device rather than mating plug and receptacle. Connector 903 comprises a housing and a plurality of lead assemblies (not shown). The housing is configured to contain and align the plurality of lead assemblies (not shown) such that an electrical connection suitable for signal communication is made between a first electrical device 910 and a second electrical device 912

FIG. 16C is a board-to-board system similar to FIG. 16A except that plug connector 905 is a vertical plug connector rather than a right angle plug connector. This embodiment makes electrical connection between two parallel electrical devices 910 and 913. A vertical back-panel receptacle connector according to the invention can be insert molded onto a board, for example. Thus, spacing, and therefore performance, can be maintained.

FIG. 17 is a perspective view of the plug connector of FIG. 16A shown without electrical devices 910 and 912 and receptacle connector 1100. As shown, slots 907 are formed in the housing 905 that contain and align the lead assemblies 908 therein. FIG. 17 also shows connection pins 932, 942. Connection pins 942 connect connector 902 to electrical device 912. Connection pins 932 electrically connect connector 902 to electrical device 910 via receptacle 1100. Connection pins 932 and 942 may be adapted to provide through-mount or surface-mount connections to an electrical device (not shown).

In one embodiment, the housing 905 is made of plastic, however, any suitable material may be used. The connections to electrical devices 910 and 912 may be surface or through mount connections.

FIG. 18 is a side view of plug connector 902 as shown in FIG. 17. As shown, the column of terminals contained in each lead assembly 908 are offset from one another column of terminals in an adjacent lead assembly by a distance D. Such an offset is discussed more fully above in connection with FIGs. 6 and 7.

FIG. 19 is a side view of a single lead assembly 908. As shown in FIG. 19, one embodiment of lead assembly 908 comprises a metal lead frame 940 and an insert molded plastic frame 933. In this manner, the insert molded lead assembly 933 serves to contain one column of terminals or conductors 930. The terminals may comprise either

differential pairs or ground contacts. In this manner, each lead assembly 908 comprises a column of differential pairs 935A and 935B and ground contacts 937.

As is also shown in FIG. 19, the column of differential pairs and ground contacts contained in each lead assembly 908 are arranged in a signal-signal-ground configuration. In this manner, the top contact of the column of terminals in lead assembly 908 is a ground contact 937A. Adjacent to ground contact 937A is a differential pair 935A comprised of a two signal contacts, one with a positive polarity and one with a negative polarity.

As shown, the ground contacts 937A and 937B extend a greater distance from the insert molded lead assembly 933. As shown in FIG. 19B, such a configuration allows the ground contacts 937 to mate with corresponding receptacle contacts 1102G in receptacle 1100 before the signal contacts 935 mate with corresponding receptacle contacts 1102S. Thus, the connected devices (not shown in FIG. 19B) can be brought to a common ground before signal transmission occurs between them. This provides for "hot" connection of the devices.

Lead assembly 908 of connector 900 is shown as a right angle module. To explain, a set of first connection pins 932 is positioned on a first plane (e.g., coplanar with first electrical device 910) and a set of second connection pins 942 is positioned on a second plane (e.g., coplanar with second electrical device 912) perpendicular to the first plane. To connect the first plane to the second plane, each conductor 930 is formed to extend a total of about ninety degrees (a right angle) to electrically connect electrical devices 910 and 912.

FIGs. 20 and 21 are side and front views, respectively, of two columns of terminals in accordance with one aspect of the invention. As shown in FIGs. 20 and 21, adjacent columns of terminals are staggered in relation to one another. In other words, an offset exists between terminals in adjacent lead assemblies. In particular and as shown in FIGs. 20 and 21, an offset of distance  $d$  exists between terminals in column 1 and terminals in column 2. As shown, the offset  $d$  runs along the entire length of the terminal. As stated above, the offset reduces the incidence of cross talk by furthering the distance between the signal carrying contacts.

To simplify conductor placement, conductors 930 have a rectangular cross section as shown in FIG. 20. Conductors 930 may, however, be any shape.

FIG. 22 is a perspective view of the receptacle portion of the connector shown in FIG. 16A. Receptacle 1100 may be mated with connector plug 902 (as shown in

FIG. 16A) and used to connect two electrical devices (not shown). Specifically, connection pins 932 (as shown in FIG. 17) may be inserted into apertures 1142 to electrically connect connector 902 to receptacle 1100. Receptacle 1100 also includes alignment structures 1120 to aid in the alignment and insertion of connector 900 into  
5 receptacle 1100. Once inserted, structures 1120 also serve to secure the connector once inserted into receptacle 1100. Such structures 1120 thereby prevent any movement that may occur between the connector and receptacle that could result in mechanical breakage therebetween.

Receptacle 1100 includes a plurality of receptacle contact assemblies 1160  
10 each containing a plurality of terminals (only the tails of which are shown). The terminals provide the electrical pathway between the connector 900 and any mated electrical device (not shown).

FIG. 23 is a side view of the receptacle of FIG. 22 including structures 1120, housing 1150 and receptacle lead assembly 1160. As shown, FIG. 23 also shows  
15 that the receptacle lead assemblies may be offset from one another in accordance with the invention. As stated above, such offset reduces the occurrence of multi-active cross talk as described above.

FIG. 24 is a perspective view of a single receptacle contact assembly not contained in receptacle housing 1150. As shown, the assembly 1160 includes a plurality  
20 of dual beam conductive terminals 1175 and a holder 1168 made of insulating material. In one embodiment, the holder 1168 is made of plastic injection molded around the contacts; however, any suitable insulating material may be used without departing from the scope of the invention.

FIG. 25 is a perspective view of a connector in accordance with another  
25 embodiment of the invention. As shown, connector 1310 and receptacle 1315 are used in combination to connect an electrical device, such as circuit board 1305 to a cable 1325. Specifically, when connector 1310 is mated with receptacle 1315, an electrical connection is established between board 1305 and cable 1325. Cable 1325 can then transmit signals to any electrical device (not shown) suitable for receiving such signals.

30 In another embodiment of the invention, it is contemplated that the offset distance,  $d$ , may vary throughout the length of the terminals in the connector. In this manner, the offset distance may vary along the length of the terminal as well as at either end of the conductor. To illustrate this embodiment and referring now to FIG. 26, a side view of a single column of right angle terminals is shown. As shown, the height of the

terminals in section A is height H1 and the height of the cross section of terminals in section B is height H2.

FIGs. 27 and 28 are front views of the columns of right angle terminals taken along lines A-A and lines B-B respectively. In addition to the single column of terminals shown in FIG. 26, FIGs. 27 and 28 also show an adjacent column of terminals contained in the adjacent lead assembly contained in the connector housing.

In accordance with the invention, the offset of adjacent columns may vary along the length of the terminals within the lead assembly. More specifically, the offset between adjacent columns varies according to adjacent sections of the terminals. In this manner, the offset distance between columns is different in section A of the terminals than in section B of the terminals.

As shown in FIGs. 27 and 28, the cross sectional height of terminals taken along line A-A in section A of the terminal is H1 and the cross sectional height of terminals in section B taken along line B-B is height H2. As shown in FIG. 27, the offset of terminals in section A, where the cross sectional height of the terminal is H1, is a distance D1.

Similarly, FIG. 28 shows the offset of the terminals in section B of the terminal. As shown, the offset distance between terminals in section B of the terminal is D2. Preferably, the offset D2 is chosen to minimize crosstalk, and may be different from the offset D1 because spacing or other parameters are different. The multi-active cross talk that occurs between the terminals can thus be reduced, thereby increasing signal integrity.

In another embodiment of the invention, to further reduce cross talk, the offset between adjacent terminal columns is different than the offset between vias on a mated printed circuit board. A via is conducting pathway between two or more layers on a printed circuit board. Typically, a via is created by drilling through the printed circuit board at the appropriate place where two or more conductors will interconnect.

To illustrate such an embodiment, FIG. 29 illustrates a front view of a cross section of four columns of terminals as the terminals mate to vias on an electrical device. Such an electric device may be similar to those as illustrated in FIG. 16A. The terminals 1710 of the connector (not shown) are inserted into vias 1700 by connection pins (not shown). The connection pins, however, may be similar to those shown in FIG. 17.

In accordance with this embodiment of the invention, the offset between adjacent terminal columns is different than the offset between vias on a mated printed

circuit board. Specifically, as shown in FIG. 29, the distance between the offset of adjacent column terminals is D1 and the distance between the offset of vias in an electrical device is D2. By varying these two offset distances to their optimal values in accordance with the invention, the cross talk that occurs in the connector of the invention is reduced and the corresponding signal integrity is maintained.

FIG. 30 is a perspective view of a portion of another embodiment of a right angle electrical connector 1100. As shown in FIG. 30, conductors 130 are positioned from a first plane to a second plane that is orthogonal to the first plane. Distance D between adjacent conductors 930 remains substantially constant, even though the width of conductor 930 may vary and even though the path of conductor 930 may be circuitous. This substantially constant gap D provides a substantially constant differential impedance along the length of the conductors.

FIG. 31 is a perspective view of another embodiment of a right angle electrical connector 1200. As shown in Figure 12, modules 1210 are positioned in a frame 1220 to provide proper spacing between adjacent modules 1210.

FIG. 32 is a perspective view of an alternate embodiment of a receptacle connector 1100'. As shown in FIG. 32, connector 1100' comprises a frame 1190 to provide proper spacing between connection pins 1175'. Frame 1190 comprises recesses, in which conductors 1175' are secured. Each conductor 1175' comprises a single contact interface 1191 and a connection pin 1192. Each contact interface 1191 extends from frame 1190 for connection to a corresponding plug contact, as described above. Each connection pin 1942 extends from frame 1190 for electrical connection to a second electrical device. Receptacle connector 1190 may be assembled via a stitching process.

To attain desirable gap tolerances over the length of conductors 903, connector 900 may be manufactured by the method as illustrated in FIG. 33. As shown in FIG. 33, at step 1400, conductors 930 are placed in a die blank with predetermined gaps between conductors 930. At step 1410, polymer is injected into the die blank to form the frame of connector 900. The relative position of conductors 930 are maintained by frame 950. Subsequent warping and twisting caused by residual stresses can have an effect on the variability, but if well designed, the resultant frame 950 should have sufficient stability to maintain the desired gap tolerances. In this manner, gaps between conductors 930 can be controlled with variability of tenths of thousandths of an inch.

Preferably, to provide the best performance, the current carrying path through the connector should be made as highly conductive as possible. Because the

current carrying path is known to be on the outer portion of the contact, it is desirable that the contacts be plated with a thin outer layer of a high conductivity material. Examples of such high conductivity materials include gold, copper, silver, a tin alloy.

It is to be understood that the foregoing illustrative embodiments have been  
5 provided merely for the purpose of explanation and are in no way to be construed as  
limiting of the invention. Words which have been used herein are words of description  
and illustration, rather than words of limitation. Further, although the invention has been  
described herein with reference to particular structure, materials and/or embodiments, the  
invention is not intended to be limited to the particulars disclosed herein. Rather, the  
10 invention extends to all functionally equivalent structures, methods and uses, such as are  
within the scope of the appended claims. Those skilled in the art, having the benefit of the  
teachings of this specification, may affect numerous modifications thereto and changes  
may be made without departing from the scope and spirit of the invention in its aspects.

What is claimed is:

1. An electrical connector comprising:  
a plurality of signal contacts; and  
5 a plurality of ground contacts;  
wherein the plurality of signal contacts and the plurality of ground contacts  
are arranged such that insertion loss and cross talk are limited as a result of the  
arrangement.
- 10 2. The electrical connector of claim 1, comprising a first signal contact and a  
second signal contact, the first and second signal contacts having a gap between them and  
forming a first differential signal pair, wherein a differential signal in the first differential  
signal pair produces a high field in the gap and a low field near a second differential signal  
pair that is adjacent to the first differential signal pair.
- 15 3. The electrical connector of claim 1, comprising a first signal contact that is  
edge-coupled with a second signal contact.
4. The electrical connector of claim 1, comprising an array of edge-coupled  
20 pairs of signal contacts.
5. The electrical connector of claim 1, having a communication speed of about  
10 gigabits per second.
- 25 6. The electrical connector of claim 1, having a row pitch of about 1.4 mm.
7. The electrical connector of claim 1, having a column pitch of about 2.0  
mm.
- 30 8. The electrical connector of claim 1, having a card pitch of about 25 mm.
9. The electrical connector of claim 1, comprising a housing through which the  
contacts extend.

10. The electrical connector of claim 9, wherein the housing is filled at least in part with a dielectric material that insulates the contacts.
11. The electrical connector of claim 10, wherein the dielectric material is air.
- 5 12. The electrical connector of claim 11, wherein the connector is a right angle, ball grid assembly connector.
- 10 13. The electrical connector of claim 1, having a near-end cross talk of less than about 3 percent at 40 picoseconds rise time with 63.5 mated signal pairs per linear inch.
14. The electrical connector of claim 1, having a far-end cross talk of less than 4% at 40 picoseconds rise time with 63.5 mated signal pairs per linear inch.
- 15 15. The electrical connector of claim 1, wherein the contacts are arranged to include a first differential signal pair along a first contact column and a second differential signal pair along a second contact column.
- 20 16. The electrical connector of claim 15, wherein the second differential signal pair is adjacent to the first differential signal pair and the connector is devoid of shields between the first differential signal pair and the second differential signal pair.
- 25 17. The electrical connector of claim 1, having a contact density of about 63.5 mated signal pairs per linear inch.
18. The electrical connector of claim 1, having a contact density of more than about 63.5 mated signal pairs per linear inch.
- 30 19. The electrical connector of claim 1, having an insertion loss of less than about 0.7 dB at 5GHz.
20. The electrical connector of claim 1, having an impedance match of about 100 ohm at 40 picosecond rise time.

21. An electrical connector comprising:  
a first differential signal pair; and  
a second differential signal pair positioned adjacent the first differential  
5 signal pair;  
wherein the connector is devoid of shields between the first differential  
signal pair and the second differential signal pair.
22. The electrical connector of claim 21, wherein the first differential signal  
10 pair is positioned along a first contact column and the second differential signal pair is  
positioned along a second contact column.
23. An electrical connector comprising:  
a connector housing;  
15 a first signal contact that extends through at least a portion of the housing;  
and  
a second signal contact that extends through at least a portion of the  
housing;  
wherein the first and second signal contacts have a gap between them and  
20 form a first differential signal pair, and  
wherein a differential signal in the first differential signal pair produces a  
high field in the gap and a low field near an adjacent differential signal pair.
24. An electrical connector system comprising:  
25 a plug connector having a plurality of signal contacts and a plurality of  
ground contacts; and  
a receptacle connector having a plurality of signal receptacle contacts and  
ground receptacle contacts for receiving associated signal contacts and ground contacts of  
the plug connector,  
30 wherein electrical characteristics of the connector that exist while the plug  
contact is fully mated with the receptacle connector are maintained when the plug  
connector is partially unmated with the receptacle connector.

25. The electrical connector system of claim 24, wherein the electrical characteristics include level of cross talk between adjacent signal contacts.

26. The electrical connector system of claim 24, wherein the electrical  
5 characteristics include level of loss insertion.

27. The electrical connector system of claim 24, wherein a signal contact mates with the associated signal receptacle contact in a mating direction, and the signal contact has a cross-sectional area transverse to the mating direction that is approximately the same  
10 as the combined cross-sectional area of the signal contact and the signal receptacle contact transverse to the mating direction.

28. An electrical connector comprising:  
a connector housing;  
15 a first conductor extending at least partially through the connector housing and having a first length; and  
a second conductor extending at least partially through the connector housing and having a second length,  
wherein an impedance between the first and second conductors is  
20 substantially constant along the first length and second length.

29. The electrical connector as recited in claim 28, wherein the first and second conductors are conductors of a differential signal pair and the impedance is a differential impedance.  
25

30. The electrical connector as recited in claim 28, wherein the first conductor is a signal conductor, the second conductor is a ground conductor, and the impedance is a single ended impedance.

30 31. The electrical connector as recited in claim 28, wherein the impedance varies less than ten percent along the first and second length.

32. The electrical connector as recited in claim 28, wherein the impedance varies less than five percent along the first and second length.

33. The electrical connector as recited in claim 28, wherein the first conductor comprises a first edge along the length of the first conductor, the second conductor comprises a second edge along the length of the second conductor, and a gap between the first edge and the second edge is substantially constant.

34. The electrical connector as recited in claim 33, wherein each conductor has a substantially rectangular cross section.

35. The electrical connector as recited in claim 34, wherein the width of the rectangular cross section is substantially larger than the thickness of the rectangular cross section.

36. The electrical connector as recited in claim 35, wherein the substantially constant gap is disposed between adjacent width faces of the rectangular cross section.

37. The electrical connector as recited in claim 35, wherein the substantially constant gap is disposed between adjacent thickness faces of the rectangular cross section.

38. The electrical connector as recited in claim 28, wherein the first and second conductors are conductors of a differential signal pair and further comprising:  
a plurality of differential signal pairs of conductors, each differential pair of conductors having a substantially constant impedance between the pair of conductors along the length of the pair of conductors; and  
a plurality of ground conductors, each ground conductor disposed adjacent to one of the plurality of differential signal pairs.

39. The electrical connector as recited in claim 38, wherein the plurality of ground conductors and the plurality of differential signal pairs are arranged in rows.

40. The electrical connector as recited in claim 38, wherein the plurality of ground conductors and the plurality of differential signal pairs are arranged in columns.

41. The electrical connector as recited in claim 40, wherein the gap between conductors of a differential signal pair adjacent to one ground is smaller than the gap between conductors of a differential signal pair adjacent to two grounds, thereby increasing the consistency of the differential impedance of the plurality of differential  
5 signal pairs.

42. The electrical connector as recited in claim 28, wherein  
a first portion of the first conductor is disposed in a first material having a first dielectric constant and a second portion of the first conductor is disposed in a second  
10 material having a second dielectric constant;  
a first portion of the second conductor is disposed in the first material and a second portion of the second conductor is disposed in the second material;  
the gap between the first conductor and the second conductor in the first material is a first distance and the gap between the first conductor and the second  
15 conductor in the second material is a second distance such that the impedance is substantially constant along the length of the conductors.

43. The electrical connector as recited in claim 42, wherein the first material comprises air and the second material comprises a polymer.  
20

44. The electrical connector as recited in claim 42, wherein the first conductor comprises a first edge along the length of the first conductor, the second conductor comprises a second edge along the length of the conductor, and a gap between the first edge and the second edge is substantially constant.  
25

45. The electrical connector as recited in claim 28, wherein the first and second conductor culminate in a blade.

46. The electrical connector as recited in claim 28, wherein the first and second  
30 conductor culminate in two single beam contacts.

47. The electrical connector as recited in claim 28, wherein each of the first and second conductors enter the connector at a first plane and exit the connector at a second plane substantially orthogonal to the second plane.

48. An electrical connector comprising:  
a first section comprising:  
a first conductor having a first length; and  
5 a second conductor having a second length, the impedance between  
the first and second conductor being substantially constant along the first and second  
length; and  
a second section comprising:  
a third conductor having a third length and adapted to receive a  
10 portion of the first conductor; and  
a fourth conductor having a fourth length and adapted to receive a  
portion of the second conductor, the impedance between the third and fourth conductor  
being substantially constant along the third and fourth length,  
wherein electrical characteristics of the connector that exist while the  
15 conductors are fully mated are maintained when the conductors are partially unmated.

49. The electrical connector as recited in claim 48 wherein the first and second  
conductor culminates in a blade and the third and fourth conductor each culminate in two  
single beam contacts for receiving the blades of the first and second conductors,  
20 respectively.

50. An electrical connector comprising:  
a first contact column having a first differential signal pair; and  
a second contact column having a second differential signal pair adjacent to  
25 the first differential signal pair;  
wherein the first column is offset from the second column such that cross  
talk between the first and second differential signal pairs is limited as a result of the offset.

51. The electrical connector of claim 50 further comprising:  
30 a first ground contact positioned at a first end of the first contact column and a second  
ground contact positioned at a second end of the second contact column, wherein the  
second end of the second contact column is opposite the first end of the first contact  
column.

52. The electrical connector of claim 50 wherein the connector is a right angle connector.
53. The electrical connector of claim 50 wherein the connector is a vertical  
5 connector.
54. The electrical connector of claim 50 further comprising:  
a lead frame, each lead frame containing one column of differential signal  
pairs and ground contacts.  
10
55. The electrical connector of claim 50 wherein the connector is adapted to  
pass signals above 1 Gb/s.
56. The connector of claim 50 wherein the first differential signal pair has a gap  
15 having a gap width and the aspect ratio of column pitch to gap width is greater than about  
five.
57. The connector of claim 50 wherein the offset between adjacent columns  
varies along the length of the differential pair.
- 20 58. The connector of claim 50 wherein the offset is about 1.3 mm.
59. The connector of claim 50 wherein said connector housing further  
comprises separable plug and receptacle housings.
- 25 60. The connector of claim 50 wherein no shields are positioned between said  
columns.
61. The connector of claim 50 wherein no grounds are positioned between said  
columns.  
30
62. The connector of claim 50, further comprising ground contacts at the top  
and bottom of at least one of said columns.
63. An electrical connector comprising:

a plug comprising:

a plurality of columns of differential contact pairs disposed within the plug, each differential contact pair including a first signal contact for transmitting a signal having a first polarity and a second signal contact for transmitting a signal having a second polarity; and

a plurality of ground contacts wherein a ground contact is disposed between each differential contact pair within each column of differential contact pairs; wherein each column of differential contact pairs and ground contacts is offset from an adjacent column such that multi-active cross talk is reduced with respect to each differential contact pair; and

a receptacle electrically connected to the plug comprising:

a second plurality of columns of differential contact pairs disposed within the receptacle, each differential contact pair including a first signal contact for transmitting a signal having a first polarity and a second signal contact for transmitting a signal having a second polarity; and

a second plurality of ground contacts wherein a ground contact is disposed between each differential contact pair within each second plurality of columns of differential contact pairs;

wherein each second column of differential contact pairs and ground contacts is offset from an adjacent column such that multi-active cross talk is reduced with respect to each differential contact pair.

64. The connector of claim 63 wherein the receptacle is adapted to connect to a cable.

65. A plug for an electrical connector comprising:

a plurality of lead frames, each said lead frame comprising:  
a column of contacts arranged as:

a plurality of differential contact pairs having terminal pins at both ends thereof, each differential contact pair including a first signal contact for transmitting a signal having a first polarity and a second signal contact for transmitting a signal having a second polarity; and

a plurality of ground contacts having ground pins at both ends thereof, wherein a ground contact is disposed between each differential contact pair;

wherein said differential contact pairs and ground contacts of each said column are offset from those of an adjacent column such that multi-active cross talk is reduced with respect to each differential contact pair.

5     66.            The plug of claim 65 wherein no shields are positioned between said lead frames.

67.            The plug of claim 66 wherein no grounds are positioned between said lead frames.

10

68.            The plug of claim 65 wherein at least one of said columns of contacts includes a ground contact at the top and bottom of said column.

15

69.            An electrical connector comprising:

a plurality of lead frames, each said lead frame comprising:

a column of contacts arranged as:

a plurality of differential contact pairs having terminal pins at both ends thereof, each differential contact pair including a first signal contact for transmitting a signal having a first polarity and a second signal contact for transmitting a signal having a second polarity, opposite from said first polarity; and

20

wherein said differential contact pairs of each said column are offset from those of an adjacent column such that multi-active cross talk is reduced with respect to each differential contact pair.

25     70.            The plug of claim 69 wherein no shields are positioned between said lead frames.

71.            The plug of claim 70 wherein no grounds are positioned between said lead frames.

30

72.            The plug of claim 69 wherein the offset between different columns varies across all the columns of the plug.
